CHROMATIC POLYNOMIALS OF SOME SUNFLOWER MIXED HYPERGRAPHS

JULIAN A. ALLAGAN

Abstract. The theory of mixed hypergraph coloring was first introduced by Voloshin in 1993 and has been growing ever since. The proper coloring of a mixed hypergraph \( H = (X, C, D) \) is the coloring of the vertex set \( X \) so that no \( D \)-hyperedge is monochromatic and no \( C \)-hyperedge is polychromatic. A mixed hypergraph with hyperedges of type \( D \), \( C \) or \( B \) is commonly known as a \( D \), \( C \), or \( B \)-hypergraph respectively where \( B = C = D \). \( D \)-hypergraph colorings are the classic hypergraph colorings which have been widely studied. The chromatic polynomial \( P(H, \lambda) \) of a mixed hypergraph \( H \) is the function that counts the number of proper \( \lambda \)-colorings, which are mappings \( f : X \to \{1, 2, \ldots, \lambda\} \). A sunflower (hypergraph) with \( l \) petals and a core \( S \) is a collection of sets \( e_1, \ldots, e_l \) such that \( e_i \cap e_j = S \) for all \( i \neq j \). Recently, Walter (see [14]) published some results concerning the chromatic polynomial of some non-uniform \( D \)-sunflower. In this paper, we present an alternative proof of his result and extend his formula to those of non-uniform \( C \)-sunflowers and \( B \)-sunflowers. Some results for a new but related member of sunflowers are also presented.

1. Definitions and notations

For basic definitions of graphs and hypergraphs we refer the reader to [1, 4, 12, 15]. A hypergraph \( H \) of order \( n \) is an ordered pair \( H = (X, E) \) where \( |X| = n \) is a finite nonempty set of vertices and \( E \) is a collection of not necessarily distinct nonempty subsets of \( X \) called hyperedges. \( H \) is said to be \( k \)-uniform if the size of each of its hyperedges is exactly \( k \). A hypergraph is said to be linear if each pair of hyperedges has at most one vertex in common.

If the alternating sequence of vertices and distinct hyperedges \( v_0, e_1, v_1, \ldots, e_l, v_l \) is a hyperpath of length \( l \geq 2 \), then the hypergraph induced by the sequence of hyperedges \( e_1, \ldots, e_l \) when \( v_0 = v_l \) is called a hypercycle of length \( l \). A hypergraph in which no set of hyperedges induce a hypercycle is said to be acyclic. In this paper all hypergraphs are assumed to be connected and acyclic.

Key words and phrases. chromatic polynomials, mixed hypergraphs, non-uniform, sunflower.
The concept of mixed hypergraph colorings has been studied extensively by Voloshin [12]. A mixed hypergraph $\mathcal{H}$ with vertex set $X$ is a triple $(X, C, D)$ such that $C$ and $D$ are elements of $E$, called $C$-hyperedges and $D$-hyperedges, respectively. Elements of $C \cap D$ are called $B$-hyperedges. A proper coloring of $\mathcal{H}$ is a coloring of $X$ such that each $C$-hyperedge has at least two vertices with a common color and each $D$-hyperedge has at least two vertices with distinct colors. When the vertices of a hyperedge are all colored with the same color, the hyperedge is said to be monochromatic. In the event the vertices are all colored differently, the hyperedge is said to be polychromatic. Given the mixed hypergraph $\mathcal{H} = (X, C, D)$, when $C = \emptyset$, we write $\mathcal{H} = (X, D)$ and $\mathcal{H}$ is often called a $D$-hypergraph. In the case when $D = \emptyset$, we write $\mathcal{H} = (X, C)$ and call the resulting hypergraph a $C$-hypergraph. In the case when $C = D$, we write $\mathcal{H} = (X, B)$ and call $\mathcal{H}$ a $B$-hypergraph.

The chromatic polynomial $P(\mathcal{H}, \lambda)$ of a mixed hypergraph $\mathcal{H}$ is the function that counts the number of proper $\lambda$-colorings, which are mappings, $f : X \rightarrow \{1, 2, \ldots, \lambda\}$ with the condition that no $C$-hyperedge is polychromatic and no $D$-hyperedge is monochromatic.

We note that while $D$-hyperedges may be of size 2, hyperedges of types $C$ or $B$ are of size at least size 3 since every $C$-hyperedge of size 2 may be contracted to a single vertex and every $B$-hyperedge of size 2 is uncolorable. We encourage the reader to refer to [5, 6, 13, 10, 12] for detailed information about chromatic polynomials, research, and applications of mixed hypergraph colorings.

For simplicity, throughout this paper, we denote the falling factorial

$$\lambda^t = \lambda(\lambda - 1)(\lambda - 2) \ldots (\lambda - t + 1).$$

2. Chromatic polynomial of some linear mixed hypergraphs

We begin this section with some known results ([2]) concerning the chromatic polynomials of some linear acyclic mixed hypergraphs also known as (linear) mixed hypertrees. We denote by $\mathcal{H}^l = (X, E)$, a hypergraph of length $l$, where $|E|=l$.

**Theorem 2.1.** Let $\mathcal{H}^l = (X, D)$ be any $D$-hypertree. Then

$$P(\mathcal{H}^l, \lambda) = \lambda \prod_{e \in D} \left(\lambda^{|e| - 1} - 1\right).$$

The result follows from the fact that there are $\lambda^{|e|} - \lambda = \lambda(\lambda^{|e| - 1} - 1)$ ways to properly color each hyperedge $e \in D$. Similar arguments as in the previous theorem are used in [2] to obtain the next two results.

**Theorem 2.2.** Let $\mathcal{H}^l = (X, C)$ be any $C$-hypertree. Then

$$P(\mathcal{H}^l, \lambda) = \lambda \prod_{e \in C} \left(\lambda^{|e| - 1} - (\lambda - 1)^{|e| - 1}\right).$$
Theorem 2.3. Let $\mathcal{H}^l = (X, \mathcal{B})$ be any $\mathcal{B}$-hypertree. Then

$$P(\mathcal{H}^l, \lambda) = \lambda \prod_{e \in \mathcal{B}} (\lambda^{|e|}-1 - (\lambda - 1)^{|e|}-1).$$

The next corollaries concern uniform mixed hypertrees and they follow respectively from Theorems 2.1, 2.2 and 2.3 when $|e| = k$ for each $e \in \mathcal{E}$.

Corollary 2.4. Let $\mathcal{H}^l = (X, \mathcal{D})$ be a $k$-uniform $\mathcal{D}$-hypertree. Then

$$P(\mathcal{H}^l, \lambda) = \lambda (\lambda^k - 1)^l.$$ 

Corollary 2.5. Let $\mathcal{H}^l = (X, \mathcal{C})$ be a $k$-uniform $\mathcal{C}$-hypertree. Then

$$P(\mathcal{H}^l, \lambda) = \lambda (\lambda^k - (\lambda - 1)^{k-1})^l.$$ 

Corollary 2.6. Let $\mathcal{H}^l = (X, \mathcal{B})$ be a $k$-uniform $\mathcal{B}$-hypertree. Then

$$P(\mathcal{H}^l, \lambda) = \lambda (\lambda^k - (\lambda - 1)^{k-1} - 1)^l.$$ 

3. Chromatic polynomial of some (strong) sunflowers

A sunflower (hypergraph) $\mathcal{H}^l = (X, \mathcal{E})$ (also known as a $\Delta$-system in [7]) with $i$ petals and a core $S$ is a collection of sets $e_1, \ldots, e_l$ such that $e_i \cap e_j = S$ for all $i \neq j$. The elements of the core are called seeds. A Venn diagram of these sets would look like a sunflower. Observe that any family of pairwise disjoint sets is a sunflower (with an empty core) and a hyperstar is a sunflower with a core of size 1. Figure 1 is an example of a 5-uniform sunflower with a core $S$ of size 3 having $e_1, e_2$ and $e_3$ as petals.

![Figure 1: A 5-uniform sunflower](image-url)

The Erdos–Rado sunflower lemma gives a necessary condition for the existence of a sunflower given any collection of uniform sets. This condition
is a lower bound for the cardinality of the collection; it is not known if the bound is the best possible [7]. We restate the lemma without proof, which can be proven by induction on $k$.

**Lemma 3.1 (Sunflower Lemma).** Given any collection of $n$ distinct sets of size $k$ (from a universal set) with $n > k! (l - 1)^k$, there is a subcollection of $l$-sets that forms a sunflower.

Our results assume sunflower mixed hypergraphs with a core $S$ and petals $\{e_1, \ldots, e_l\}$ such that $|S| \leq |e_i| - 1$ for $1 \leq i \leq l$. We begin with a recent result of Walter [14] about sunflowers with petals of type $D$. Note that when $|S| = 1$, it is easy to verify that we obtain the formula of a $D$-hypertree. In particular, the chromatic polynomial of a $D$-hyperstar.

**Theorem 3.2.** [14] Let $H^l = (X, D)$ be any $D$-sunflower. Then

$$P(H^l, \lambda) = \lambda^n - \lambda^{n-|S|+1} + \lambda \prod_{e \in D} (\lambda^{|e|-|S|} - 1).$$

**Proof.** Suppose the core is monochromatic. Then there are $\lambda^{|e|-|S|} - 1$ ways to color the remaining vertices of each petal so that no petal is monochromatic, giving $\lambda \prod_{e \in D} (\lambda^{|e|-|S|} - 1)$ proper colorings. Otherwise, there are $\lambda^{|S|} - \lambda$ ways to color the core. For each such coloring there are $\lambda^{|e|-|S|}$ ways to color the remaining vertices of each petal $e \in D$, giving $\prod_{e \in D} \lambda^{|e|-|S|} (\lambda^{|S|} - \lambda)$ proper colorings. Furthermore, since $n = |S| + \sum_{e \in D} (|e| - |S|)$, the result gives all proper colorings. 

As mentioned earlier, the previous result was first established by Walter as the chromatic polynomial of non-uniform $D$-sunflowers (albeit using a substantially different argument) to extend Tomescu’s result for uniform $D$-sunflowers [9]. We present Tomescu’s result in the following corollary with a slightly different notation by assuming that $|S| = k - p$ for $2 \leq k < p$. This result follows from Theorem 3.2 when $|e| = k$ for each $e \in D$.

**Corollary 3.3.** Let $H^l = (X, D)$ be a $k$-uniform $D$-sunflower. Then

$$P(H^l, \lambda) = \lambda^n - \lambda^{n-k+p+1} + \lambda (\lambda - 1)^l.$$

Results similar to Theorem 3.2 and Corollary 3.3 have been recently established by White in the form of multivariate polynomials using a deletion-contraction-extraction recurrence. For detailed results of his technique and proofs, see [16]. Our next results address sunflower mixed hypergraphs with petals of the same type $C$ or $B$. A similar counting argument as in Theorem 3.2 is used to prove the next theorem.

**Theorem 3.4.** Let $H^l = (X, C)$ be any $C$-sunflower. Then

$$P(H^l, \lambda) = \lambda^n - \lambda^{|S|} \prod_{e \in C} \lambda^{|e|-|S|} + \lambda^{|S|} \prod_{e \in C} (\lambda^{|e|-|S|} - (\lambda - |S|)^{|e|-|S|}).$$
Proof. Suppose the core is polychromatic. There are \( \lambda^{|S|} \) ways to color its seeds. For each such coloring, there are \( \lambda^{|e| - |S|} - (\lambda - |S|)^{|e| - |S|} \) ways to color the remaining vertices of each petal so that no petal is polychromatic, giving the last term. Otherwise, there are \( \lambda^{|S|} - \lambda^{|S|} \) ways to color the core, giving the first two terms after an expansion.

Observe that when \(|S| = 1\), the previous result gives the chromatic polynomial of a \( C \)-hyperstar.

In the next theorem, we assume \(|S| \geq 2\). When \(|S| = 1\), we refer the reader to the result of Theorem 2.3, which is equivalent to that of a \( B \)-hyperstar.

**Theorem 3.5.** Let \( \mathcal{H}^l = (X, \mathcal{B}) \) be any \( \mathcal{B} \)-sunflower. Then

\[
P(\mathcal{H}^l, \lambda) = \lambda^n - (\lambda^{|S|} + \lambda) \prod_{e \in \mathcal{B}} \lambda^{|e| - |S|} + \lambda \prod_{e \in \mathcal{B}} (\lambda^{|e| - |S|} - 1) + \lambda^{|S|} \prod_{e \in \mathcal{B}} (\lambda^{|e| - |S|} - (\lambda - |S|)^{|e| - |S|}).
\]

Proof. Given any proper coloring of \( \mathcal{H}^l \), one of the following is true:

1. The core is polychromatic giving \( \lambda^{|S|} \) colorings. For each such coloring, there are \( \lambda^{|e| - |S|} - (\lambda - |S|)^{|e| - |S|} \) ways to color the remaining vertices of each petal so that no petal is polychromatic, giving the last term. The condition that \(|S| \geq 2\) ensures that no hyperedge of \( \mathcal{H}^l \) is monochromatic in this case.
2. The core is monochromatic giving \( \lambda \) colorings. For each such coloring, there are \( \lambda^{|e| - |S|} - 1 \) ways to color the remaining vertices of each petal so that no petal is monochromatic, giving the third term.
3. The core is neither polychromatic nor monochromatic giving \( \lambda^{|S|} - \lambda^{|S|} - \lambda \) colorings. For each such coloring, there are \( \lambda^{|e| - |S|} \) ways to color the remaining vertices of each petal, giving the first two terms after an expansion.

The following corollaries follow respectively from Theorems 3.4 and 3.5 when for each \( e \in \mathcal{E} \), \(|e| = k\) and \(|S| = k - p\) with \( k \geq 3\). We note that \( n = k - p + pl \).

**Corollary 3.6.** Let \( \mathcal{H}^l = (X, \mathcal{C}) \) be a \( k \)-uniform \( C \)-sunflower. Then

\[
P(\mathcal{H}^l, \lambda) = \lambda^n + \lambda^{k-p}((\lambda^p - (\lambda - k + p)^p)^l - \lambda^p).
\]

**Corollary 3.7.** Let \( \mathcal{H}^l = (X, \mathcal{B}) \) be a \( k \)-uniform \( \mathcal{B} \)-sunflower. Then

\[
P(\mathcal{H}^l, \lambda) = \lambda^n + \lambda^{k-p}((\lambda^p - (\lambda - k + p)^p)^l - \lambda^p) - \lambda^{p+1} + \lambda(\lambda^p - 1)^l.
\]

We define a \( \mu \)-linear set to be a collection of nonempty sets such that the intersection of any pair of its member is either trivial or \( \mu \). Thus, a sunflower with core size \( \mu \) is a \( \mu \)-linear set (or hypergraph). When \( \mu = 1 \), a 1-linear hypergraph is simply called a linear hypergraph. On the other hand, we
define a set to be $\mu$-nonlinear when the cardinality of the intersection of any pair of its members is at most $\mu > 1$. Simply put, any collection of sets is either $\mu$-linear or $\mu$-nonlinear for some $\mu$.

The problem of finding the chromatic polynomial of $\mu$-linear or $\mu$-nonlinear hypergraphs of arbitrary length when $\mu > 1$ is NP hard [3]. Currently we are unaware of any known formulae for either family besides the ones we presented or quoted in this paper so far. To encourage further work in this direction, in the following section we introduce an acyclic hypergraph whose chromatic polynomial we explicitly obtained when $\mu = 1$ and 2.

4. Chromatic polynomial of some weak sunflowers

A transversal (or blocking set) of $\mathcal{F} = \{e_1, \ldots, e_l\}$ is a set which intersects every member of $\mathcal{F}$ (obviously, $\mathcal{F}$ can have more than one transversal). A transversal of $\mathcal{F}$ with the least number of elements is often referred to as a covering set and its cardinality is called a covering number (or blocking number). The core $S$ of a sunflower is a transversal and $S$ is a covering set if $|S| = 1$. Let $\mathcal{F} = \{e_1, \ldots, e_l\}$ be a collection of pairwise disjoint sets and we denote by $S$ a transversal of the collection. We call $S$ the core of the collection and its elements are the seeds. The members of the collection will be referred to as petals. Thus, it is natural to refer to the hypergraph $\mathcal{H}_l = (X, \mathcal{E})$ with $\mathcal{E} = S \cup \mathcal{F}$ as a weak sunflower with $l$-petals. Figure 2 is a representation of a 4-uniform weak sunflower with a core $S$ of size 6 having petals $e_1$, $e_2$ and $e_3$.

![Figure 2: A 4-uniform weak sunflower](attachment:figure2.png)

Just as the Erdos–Rado sunflower lemma gives a necessary condition for the existence of a (strong) sunflower, it will be interesting to find a condition on the existence of a weak sunflower given a collection of $n$ distinct $k$-uniform
sets. We assume $|e_i \cap S| = \mu$ and discuss the chromatic polynomials of some weak sunflowers when $\mu = 1$ and 2. When $\mu = 1$, we obtain the formulae for linear acyclic mixed hypergraphs of length $l + 1$ in the following theorems. We assume $|S| = 2$ and each petal $e_1, \ldots, e_l$ is of the same type, $D$, $C$ or $B$. When the petals are of type $D$, we assume $|e_i| \geq 2$. When the petals are of type $B$ or $C$, we assume $|e_i| \geq 3$.

**Theorem 4.1.** Let $\mathcal{H}^l = (X, D)$ be a linear weak $D$-sunflower. Then for all $l \geq 1$,

$$P(\mathcal{H}^l, \lambda) = (\lambda^{|S|} - \lambda) \prod_{e \in D} (\lambda^{|e|} - 1).$$

**Proof.** There are $\lambda^{|S|} - \lambda$ ways to color the seeds of the core such that they are not monochromatic. For each such coloring, there are $\lambda^{|e|} - 1$ ways to color the remaining $|e| - 1$ vertices of each disjoint petal so that no petal is monochromatic as well. □

The next two results follow a similar counting argument as in Theorem 4.1 when considering petals of types $C$ and $B$ respectively.

**Theorem 4.2.** Let $\mathcal{H}^l = (X, C)$ be a linear weak $C$-sunflower. Then for all $l \geq 1$,

$$P(\mathcal{H}^l, \lambda) = (\lambda^{|S|} - \lambda^{|S|}) \prod_{e \in C} (\lambda^{|e|} - 1 - (\lambda - 1)^{|e| - 1}).$$

**Proof.** There are $\lambda^{|S|} - \lambda^{|S|}$ ways to color the seeds so that they are not polychromatic. For each such coloring, there are $\lambda^{|e|} - 1 - (\lambda - 1)^{|e| - 1}$ ways to color the remaining $|e| - 1$ vertices of each disjoint petal so that no petal is polychromatic. □

**Theorem 4.3.** Let $\mathcal{H}^l = (X, B)$ be a linear weak $B$-sunflower. Then for all $l \geq 1$,

$$P(\mathcal{H}^l, \lambda) = (\lambda^{|S|} - \lambda^{|S|} - \lambda) \prod_{e \in B} (\lambda^{|e|} - 1 - (\lambda - 1)^{|e| - 1} - 1).$$

**Proof.** There are $\lambda^{|S|} - \lambda^{|S|} - \lambda$ ways to color the seeds so that they are neither monochromatic nor polychromatic. For each such coloring, there are $\lambda^{|e|} - 1 - (\lambda - 1)^{|e| - 1} - 1$ ways to color the remaining $|e| - 1$ vertices of each disjoint petal. □

Suppose $\mathcal{H}^l = (X, \mathcal{E})$ is a weak sunflower mixed hypergraph with a set of petals $\{e_1, \ldots, e_l\}$ such that $|e| = k$ for every $e \in \mathcal{E}$. If $|S| = k$ then $\mathcal{H}^l$ is said to be $k$-uniform. The case when $S$ is a covering set (i.e., when $|S| = l$), we simply let $l = k$. The following corollaries follow respectively from Theorems 4.1, 4.2 and 4.3 when $|S| = |e| = k$ for each $e \in \mathcal{E}$.

**Corollary 4.4.** Let $\mathcal{H}^l = (X, D)$ be a linear $k$-uniform weak $D$-sunflower. Then for all $l \geq 1$,

$$P(\mathcal{H}^l, \lambda) = \lambda(\lambda^{k-1} - 1)^{l+1}.$$
Corollary 4.5. Let $\mathcal{H}^l = (X, C)$ be a linear $k$-uniform weak $C$-sunflower. Then for all $l \geq 1$,

$$P(\mathcal{H}^l, \lambda) = \lambda(\lambda^{k-1} - (\lambda - 1)^{(k-1)})^{l+1}.$$  

Corollary 4.6. Let $\mathcal{H}^l = (X, B)$ be a linear $k$-uniform weak $B$-sunflower. Then for all $l \geq 1$,

$$P(\mathcal{H}^l, \lambda) = \lambda(\lambda^{k-1} - (\lambda - 1)^{(k-1)} - 1)^{l+1}.$$  

The arguments previously used in finding the chromatic polynomials of linear weak sunflowers cannot be extended to find the chromatic polynomial of any 2-linear weak sunflower. We use an inductive argument to establish the recursion in the next theorem. The result assumes that each hyperedge and core is of type $D$. Although the argument can be extended to each hyperedge and core of type $C$ or $B$ as well.

Theorem 4.7. Suppose $\mathcal{H}^l = (X, D)$ is a 2-linear weak sunflower. Then for all $l \geq 1$,

$$P(\mathcal{H}^l, \lambda) = (\lambda^{e_1|-2| - 1})P(\mathcal{H}^{l-1}, \lambda) + \lambda^2\lambda^{|S|+|S|-4} \prod_{i=1}^{l-1} (\lambda^{e_i} - \lambda).$$

Proof. When $l = 1$ we let $S \cap e_1 = \{u, v\}$. We count the cases when $f(u) = f(v)$ and when $f(u) \neq f(v)$ separately as follows:

Case 1: $f(u) = f(v)$.

We identify $u$ and $v$ as a new vertex giving $\lambda(\lambda^{e_1|-2| - 1})(\lambda^{|S|-2} - 1)$ colorings.

Case 2: $f(u) \neq f(v)$.

We connect $u$ and $v$ with an edge. In this case, having satisfied the necessary condition for a proper coloring of both $S$ and $e_1$, we proceed to color their remaining vertices with no restriction to obtain $\lambda^2\lambda^{|S|+|S|-4}$ colorings. Thus, the number of colorings when $l = 1$ is given by

$$P(\mathcal{H}^1, \lambda) = \lambda(\lambda^{e_1|-2| - 1})(\lambda^{|S|-2} - 1) + \lambda^2\lambda^{|S|+|S|-4}.$$  

This formula is supported by the expression in the theorem when $l = 1$ since $P(\mathcal{H}^0, \lambda) = \lambda(\lambda^{|S|-2} - 1)$.

For $l \geq 2$, we let $S \cap e_1 = \{u, v\}$ and assume that $P(\mathcal{H}^{l-1}, \lambda)$ counts the number of proper colorings of a weak sunflower with $l - 1$ petals. Similar to the base case, in any proper coloring of $H^l$, one of the following must be true:

Case 1: $f(u) = f(v)$.

We identify $u$ and $v$ by a new vertex $w$ as the intersection of both $e_1$ and $S$. For each coloring $f$ of the $P(\mathcal{H}^{l-1}, \lambda)$ proper colorings of $\mathcal{H}^{l-1}$, there exists $\lambda^{e_1|-2| - 1}$ colorings of $V(e_1) \setminus w$, giving the first term.

Case 2: $f(u) \neq f(v)$.
For any proper coloring of the remaining \(|e_i| + |S| - 4\) vertices of both \(S\) and \(e_i\), we have \(\lambda^{e_i} - \lambda\) ways to color the vertices of each disjoint petal \(e_1, \ldots, e_{l-1}\), giving the second term. The result follows.

\[\square\]

The next corollary follows from Theorem 4.7 when equation (4.1) is used as the standard basis for the recursion.

**Corollary 4.8.** Let \(H^l = (X, D)\) be a 2-linear weak sunflower. Then
\[
P(H^l, \lambda) = \lambda(\lambda^{|S|-2} - 1) \prod_{1 \leq i \leq l} (\lambda^{|e_i|-2} - 1) + \sum_{1 \leq i \leq l} \Phi(\lambda, i) \prod_{i+1 \leq j \leq l} (\lambda^{|e_j|-2} - 1)(\lambda^{|e_i|} - \lambda)
\]
for all \(l \geq 1\) where
\[
\Phi(\lambda, i) = \lambda^{|e_i|+|S|-2i} - \lambda^{|e_i|+|S|-2i-1}.
\]

When \(|e_i| = |S| = k\) for all \(i = 1, \ldots, l\), we obtain from Corollary 4.8 the next result.

**Corollary 4.9.** Let \(H^l = (X, D)\) be a \(k\)-uniform 2-linear weak sunflower. Then
\[
P(H^l, \lambda) = \lambda(\lambda^{k-2} - 1)^{l+1} + \sum_{1 \leq i \leq l} (\lambda^{2k-2i} - \lambda^{2k-2i-1})(\lambda^k - \lambda)^{i-1}(\lambda^{k-2} - 1)^{l-i}
\]
for all \(l \geq 1\).

Further chromatic polynomial formulae can be derived using similar arguments as in the previous theorems by considering the core of a sunflower to be of a different type (\(D, C\) or \(B\)) when compared to its petals.

Two mixed hypergraphs \(H_1\) and \(H_2\) are **chromatically equivalent** or simply **\(\chi\)-equivalent** if \(P(H_1, \lambda) = P(H_2, \lambda)\) and we write \(H_1 \sim H_2\). A mixed hypergraph \(H\) is **\(\chi\)-unique** if \(H' \sim H\) implies that \(H'\) is isomorphic to \(H\). The chromaticity of a mixed hypergraph studies whether a mixed hypergraph \(H\) is \(\chi\)-unique. In other words, does \(P(H, \lambda)\) provide enough information so that \(H\) is uniquely determined? Attempting to answer this question for \(\mu\)-(non)linear mixed hypergraphs is not easy, although Tomescu [8, 9] had shown that \(D\)-sunflowers are chromatically unique in general. Further work still needs to be done with regard to the chromaticity of mixed sunflowers with hyperedges of type \(C\) or \(B\). Although it is not too difficult to see that acyclic mixed hypergraphs are not \(\chi\)-unique in general, it remains unclear what can be said about the class of mixed hypergraphs that are chromatically equivalent to \(\mu\)-(non)linear acyclic mixed hypergraphs. Indeed, a weak sunflower with \(l\) petals is isomorphic to a \(\mu\)-linear hyperpath of length \(l \leq 3\) and a strong sunflower with \(l\) petals is isomorphic to a \(\mu\)-linear hyperpath of length \(l \leq 2\). We also hope that further work can be done to compare the chromatic polynomial of some 2-linear acyclic hypergraph of length \(l > 3\) to
that of a 2-linear weak sunflower with the goal of finding the formulae for
other members of both $\mu$-linear and $\mu$-nonlinear mixed hypergraphs when
$\mu > 1$.

Acknowledgments

The author wishes to thank the anonymous referee for helpful comments
and suggestions, and he is particularly grateful for the careful reading and
corrections done by the editor of this journal.
